Exercise Lecture VI:
again on classical numerical integration (gaussian quadrature); gaussian distribution and central limit theorem

1. **1D "classical" integration: Gaussian Quadrature**

   Remind the Gauss-Legendre rule for *quadrature* with non equispaced points:

   $$\int_a^b f(x)dx \approx \sum_{i=1}^n w(i)f(x(i))$$

   For integration in [-1,1], x_i are the roots of the Legendre polynomials: abscissas and weights up to the fourth order, and the degree of the polynomial exactly integrable are listed in the following tables:

n	i	x_i	w_i	degree
1	1	0	2	1
2	1	-0.577350269189626	1	3
	2	0.577350269189626	1	
3	1	-0.774596669241483	0.555555555555556	5
	2	0	0.888888888888889	
	3	0.774596669241483	0.555555555555556	
4	1	-0.861136311594053	0.347854845137454	7
	2	-0.339981043584856	0.652145154862546	
	3	0.339981043584856	0.652145154862546	
	4	0.861136311594053	0.347854845137454	

   We can transform the special points and weights for integration in an arbitrary interval $[a,b]$ with the substitution ("new" refers to $[a,b]$, "old" to $[-1,1]$):

   $$x_{new} = \frac{b-a}{2}x_{old} + \frac{b+a}{2} \quad \text{and} \quad w_{new} = \frac{b-a}{2}w_{old}$$

(a) Consider once again the definite integral

$$I = \int_0^1 e^x \, dx = e - 1$$

whose numerical estimate F_N has been already calculated using (1) the trapezoidal and (2) the Simpson's rule in the previous exercise session. Now we use (3) the Gauss-Legendre quadrature. Here is listed a simple program implementing explicitly the second-order formula (`gauleg-IIorder.f90`). Verify that already at this order, the Gauss-Legendre quadrature gives a very good approximation.

(b) A more general implementation of Gauss-Legendre is proposed in `gauleg-other.f90` which makes use of the subroutine `gauleg` from "Numerical Recipes" (but the code is self-contained, it can be used without any external routine/module/interface). Estimate the relative error

$$\epsilon = \left| \frac{numeric - exact}{exact} \right|$$

for the 3 different methods, considering e.g. N=2, 4, 8, 16, 32, 64. Make a log-log plot of $|\epsilon|$ as a function of N. What about the dependence of the error on N? Can you identify the range of N where the roundoff errors are dominant? (consider the possibility of increasing the precision).

(c) The program `gauleg_nr_test.f90` is another example of the use of the subroutine `gauleg` from "Numerical Recipes"; where the subroutine and other auxiliary routines/module/interface are external and must be compiled and linked. They are extracted from the "Numerical Recipes" library, properly simplified (the original versions contain more and more subroutines) and are listed at the end of these notes.

In order to use the routines of Numerical Recipes, you have to compile and link the main program with:
- the subroutine `gauleg` which gives points and abscissas
- `nrtype.f90` containing type declarations; - `nrutil.f90` containing modules and utilities; - `nr.f90` containing (through a module with `interfaces`) the conventions to call the subroutines with the main program

You must compile these files with the option `-c`: this produces `.mod` and `.o` (the objects). In a second step compile the main program. Finally you link all the files `.o` and produce the executable:
```
g95 -c nrtype.f90 nrutil.f90 nr.f90 gauleg.f90
g95 -c gauleg_nr_test.f90
g95 -o a.out gauleg_nr_test.o nrtype.o nrutil.o nr.o gauleg.o
```

2. **Random numbers with gaussian distribution: the central limit theorem**

Use the central limit theorem in order to produce random numbers with gaussian distribution. Remind that given a sequence of independent random numbers r_i, their sum

$$x_N = \sum_{i=1}^{N} r_i$$

is distributed according to

$$P_N(x) = \frac{1}{\sqrt{2\pi\sigma^2}} exp\left(-\frac{(x_N - \mu)^2}{2\sigma^2}\right)$$

with $\mu = N < r >$, $\sigma^2 = N(< r^2 > - < r >^2)$.
Furthermore, defining

$$z_N = \frac{x_N - \mu}{\sigma}$$

we have $< z_N^4 > \approx 3 < z_N^2 >^2$.

(a) Use random numbers r_i uniformly distributed in $[-1,1]$, choosing N$\approx$ 500 and generating at least $\approx$ 100 points x_N. Verify (doing an histogram) that x_N have a Gaussian distribution.

(b) Calculate numerically $< x_N >$ and σ_x^2 and compare them with μ and σ^2 analytically calculated.

(c) Consider z_N and verify numerically the relationship $< z_N^4 > \approx 3 < z_N^2 >^2$.

(d) Do again the exercise using random numbers r_i with exponential distribution ($p(r) = e^{-r}$ if $r \geq 0$, 0 elsewhere). Calculate $< x_N >$, $\sigma_{x_N}^2$ and μ, σ^2 numerically and analytically, respectively.

(e) Consider now random numbers r_i with distribution

$$p(r) = \frac{a}{\pi} \frac{1}{r^2 + a^2}$$

(Lorentz's), with $a = 1$, for instance. Do $\langle x \rangle$, $\langle x^2 \rangle$ and σ_x^2 exist?? Try to determine the characteristic of the distribution of the variable sum $x_N = \sum_{i=1}^{N} r_i$.
